The concept of stemness

The stemness gene

Fortunel et al
(ESC/NPC/RPC): 385

Ivanova et al
(ESC/NPC/HSC): 283

Itga-6

A

Ramalho-Santos et al
(ESC/NPC/HSC): 230

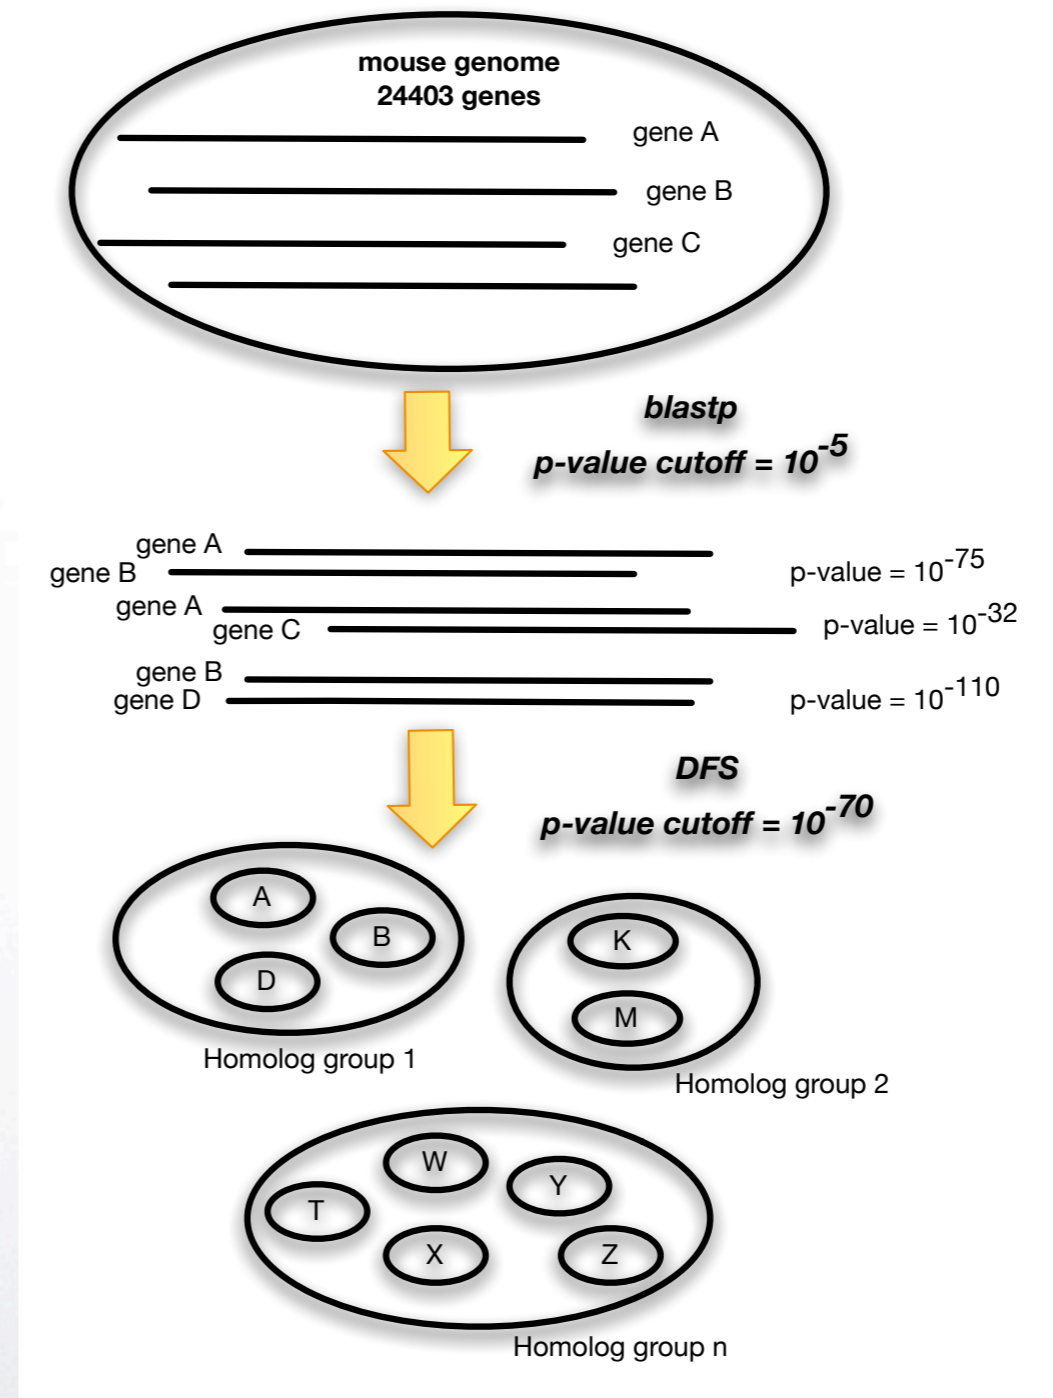

Our hypothesis

- We hypothesize that different stem cells may employ common mechanisms or pathways even though they express distinct repertoires of genes
- Global approach: identify common *homolog groups* or *pathways*

Methods

- blastp
- entire mouse proteome

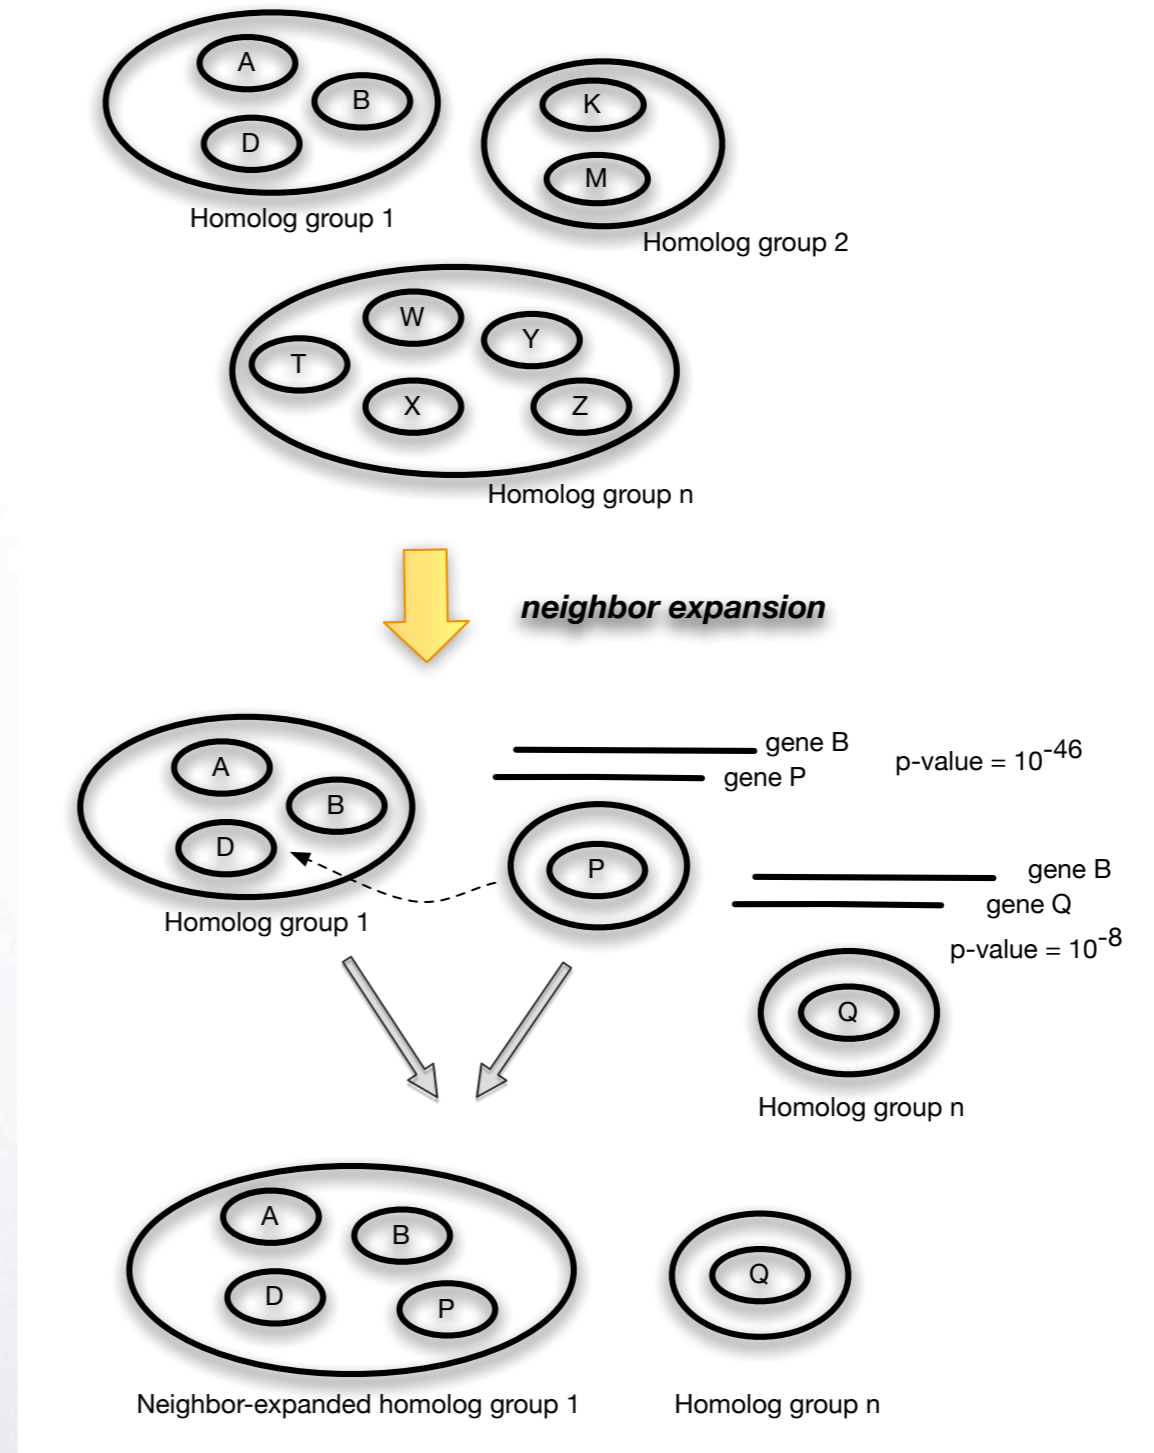

Methods

neighbor
expansion

=

homolog group
boosting with
singletons

Neighbor expansion

Statistics

Before expansion:

Mean = 5.9 genes/group,
Median = 3
Std = 30.5
Min = 2 genes/group (singletons excluded)
Max = 1008 genes/group

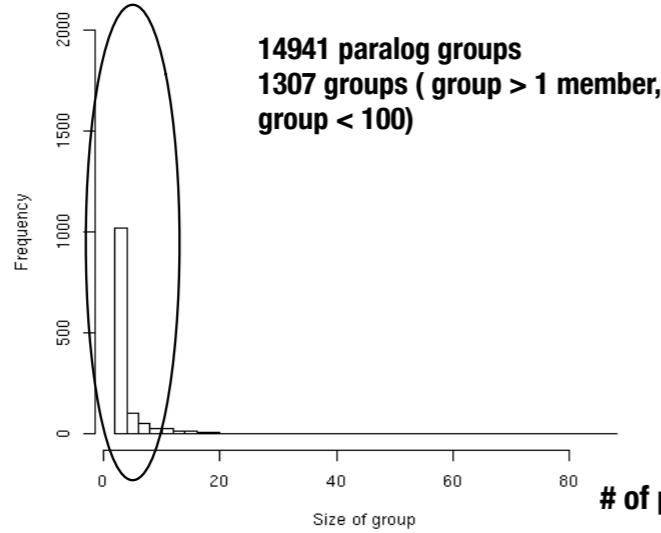

After expansion:

Mean = 4.998 genes/group
Median = 3
Std = 23.8
Min = 2 genes/group (singletons excluded)
Max = 1018 genes/group

Sizes of all paralog groups after neighbor expansion

Sizes of paralog groups with less than 100 members from strict cutoff

neighbor expansion

Sizes of paralog groups with less than 100 members after neighbor expansion

of paralog groups

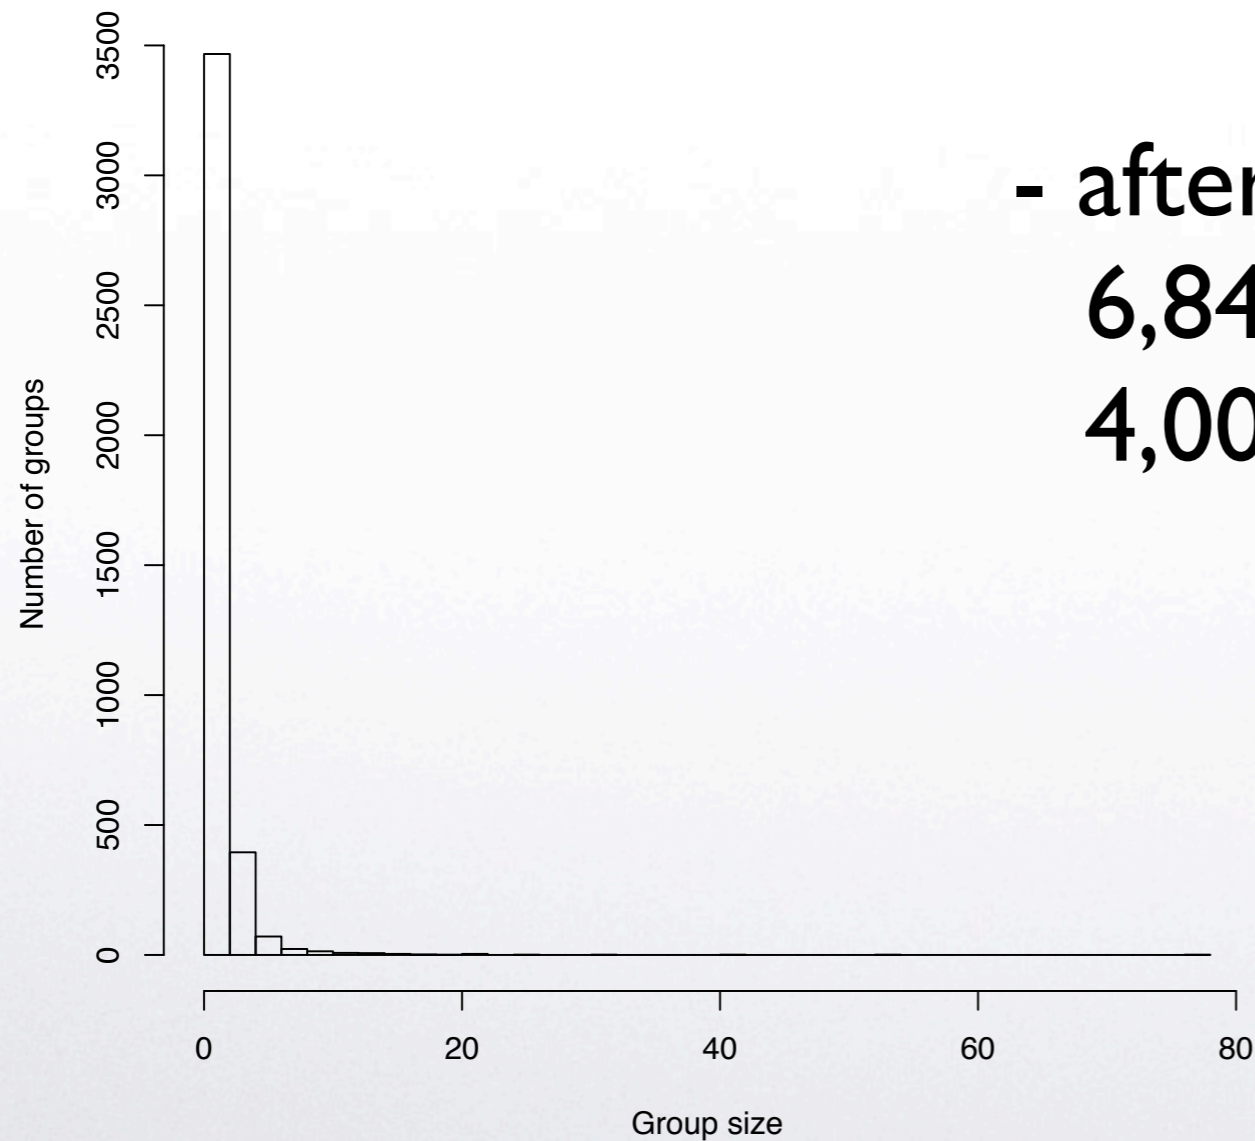

of small paralog groups

Restricted expanded groups

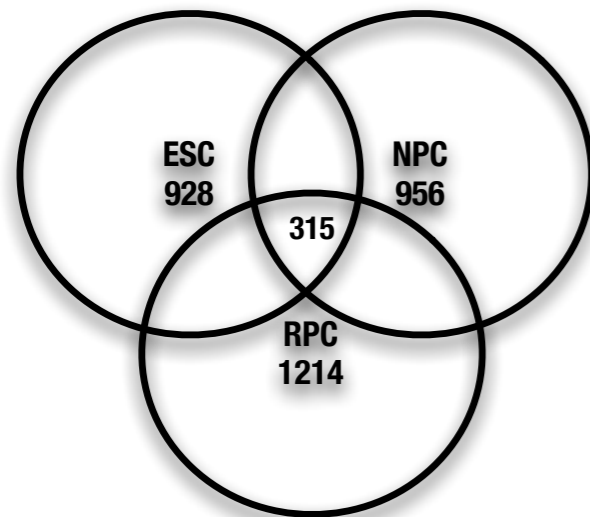

Distribution of group sizes

- after restriction to tested genes
6,843 genes
4,001 homolog groups

Common groups

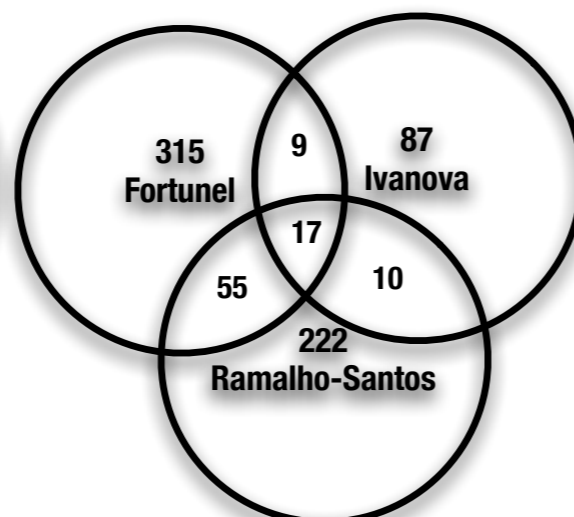

Fortunel dataset - upregulated paralog groups

Ivanova dataset - upregulated paralog groups

Ramalho-Santos dataset - upregulated paralog groups

Upregulated paralog groups between all tested datasets

17 common homolog groups to all experiments

Scoring

- Whole score types

- average score
- max score

- a gene-weighted score

- Partial score types

- between-study score
- within-study score
- between-tissue score
- within-tissue score

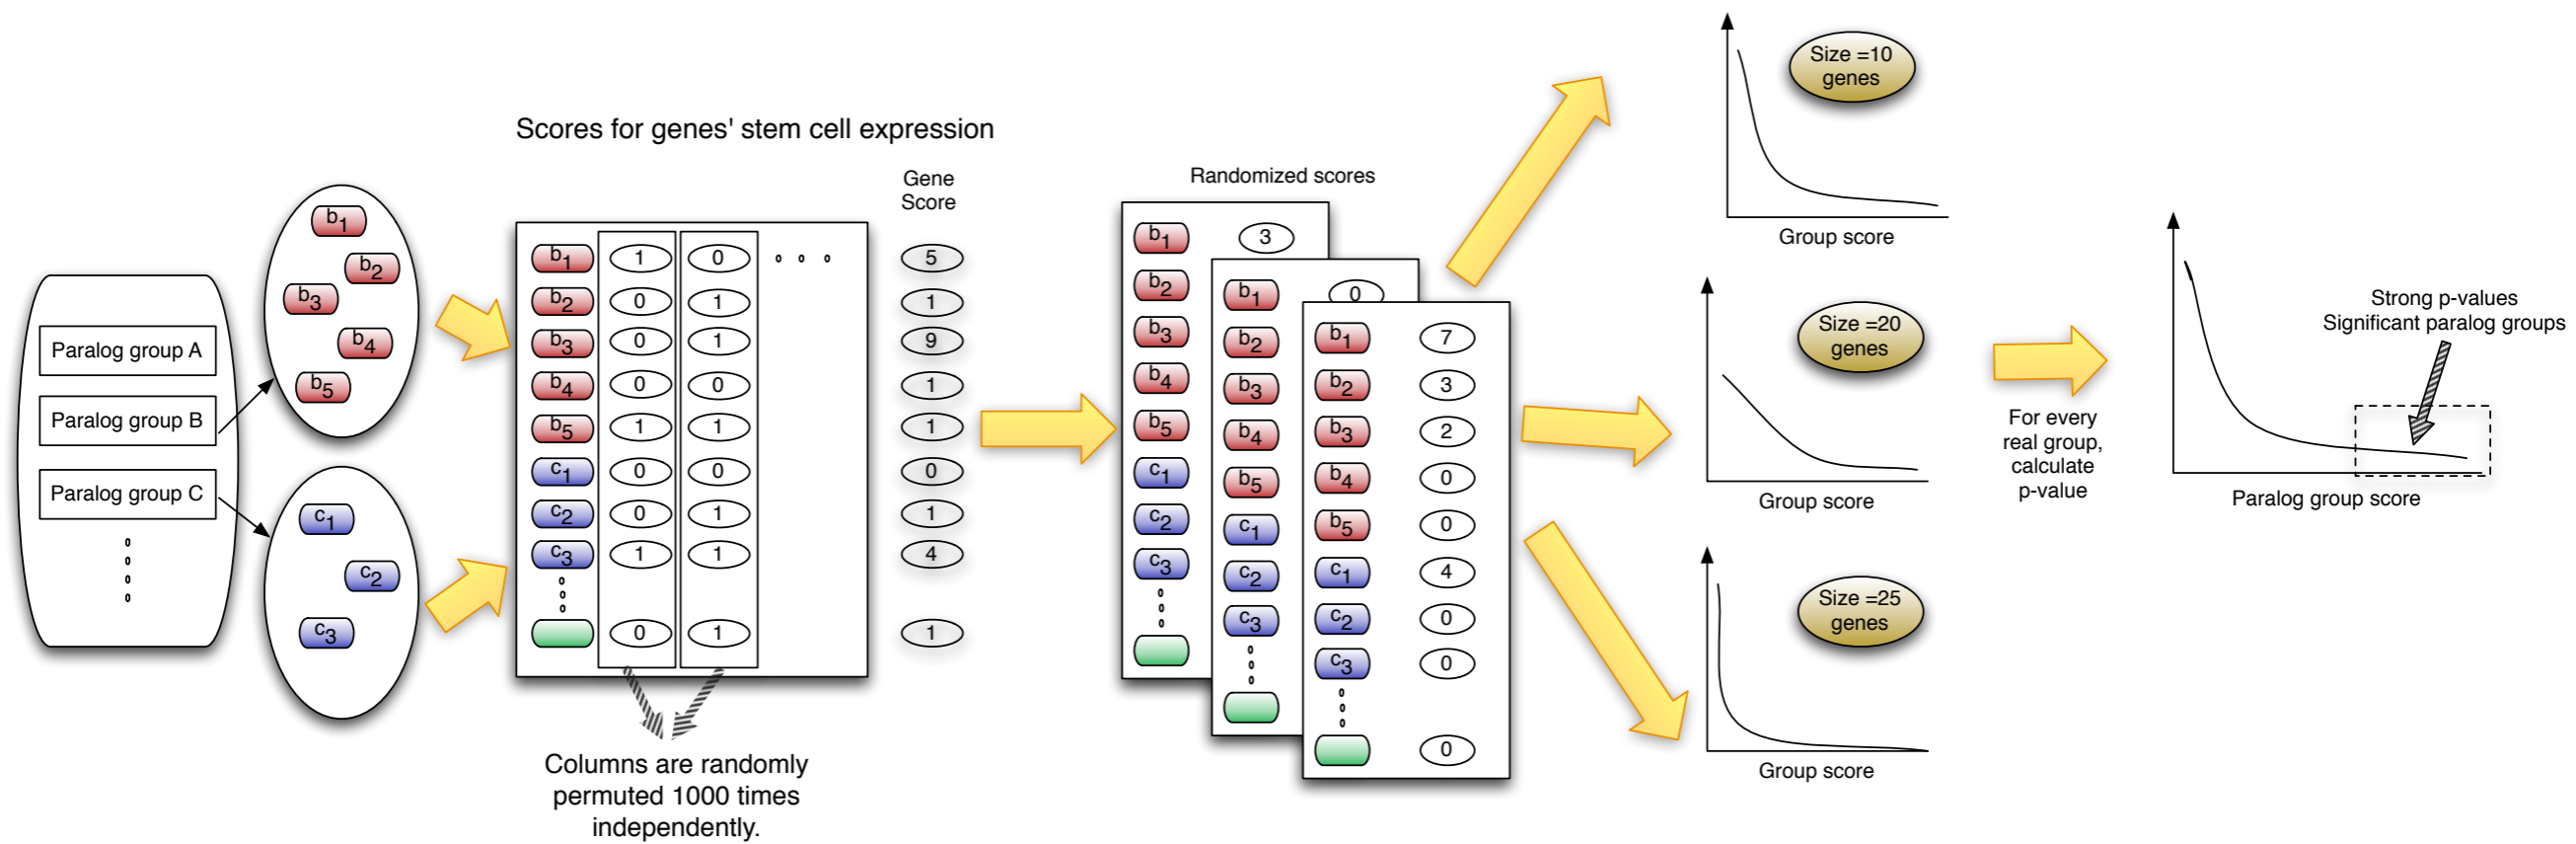

$$Score(g) = \sum_{i=1}^n \frac{(\sum_{j=1}^9 x_{ij})^2}{9}$$

n = the number of genes in group g

$$x_{ij} = \begin{cases} 1 & \text{if gene } x_i \text{ is upregulated in list } j \\ 0 & \text{otherwise} \end{cases}$$

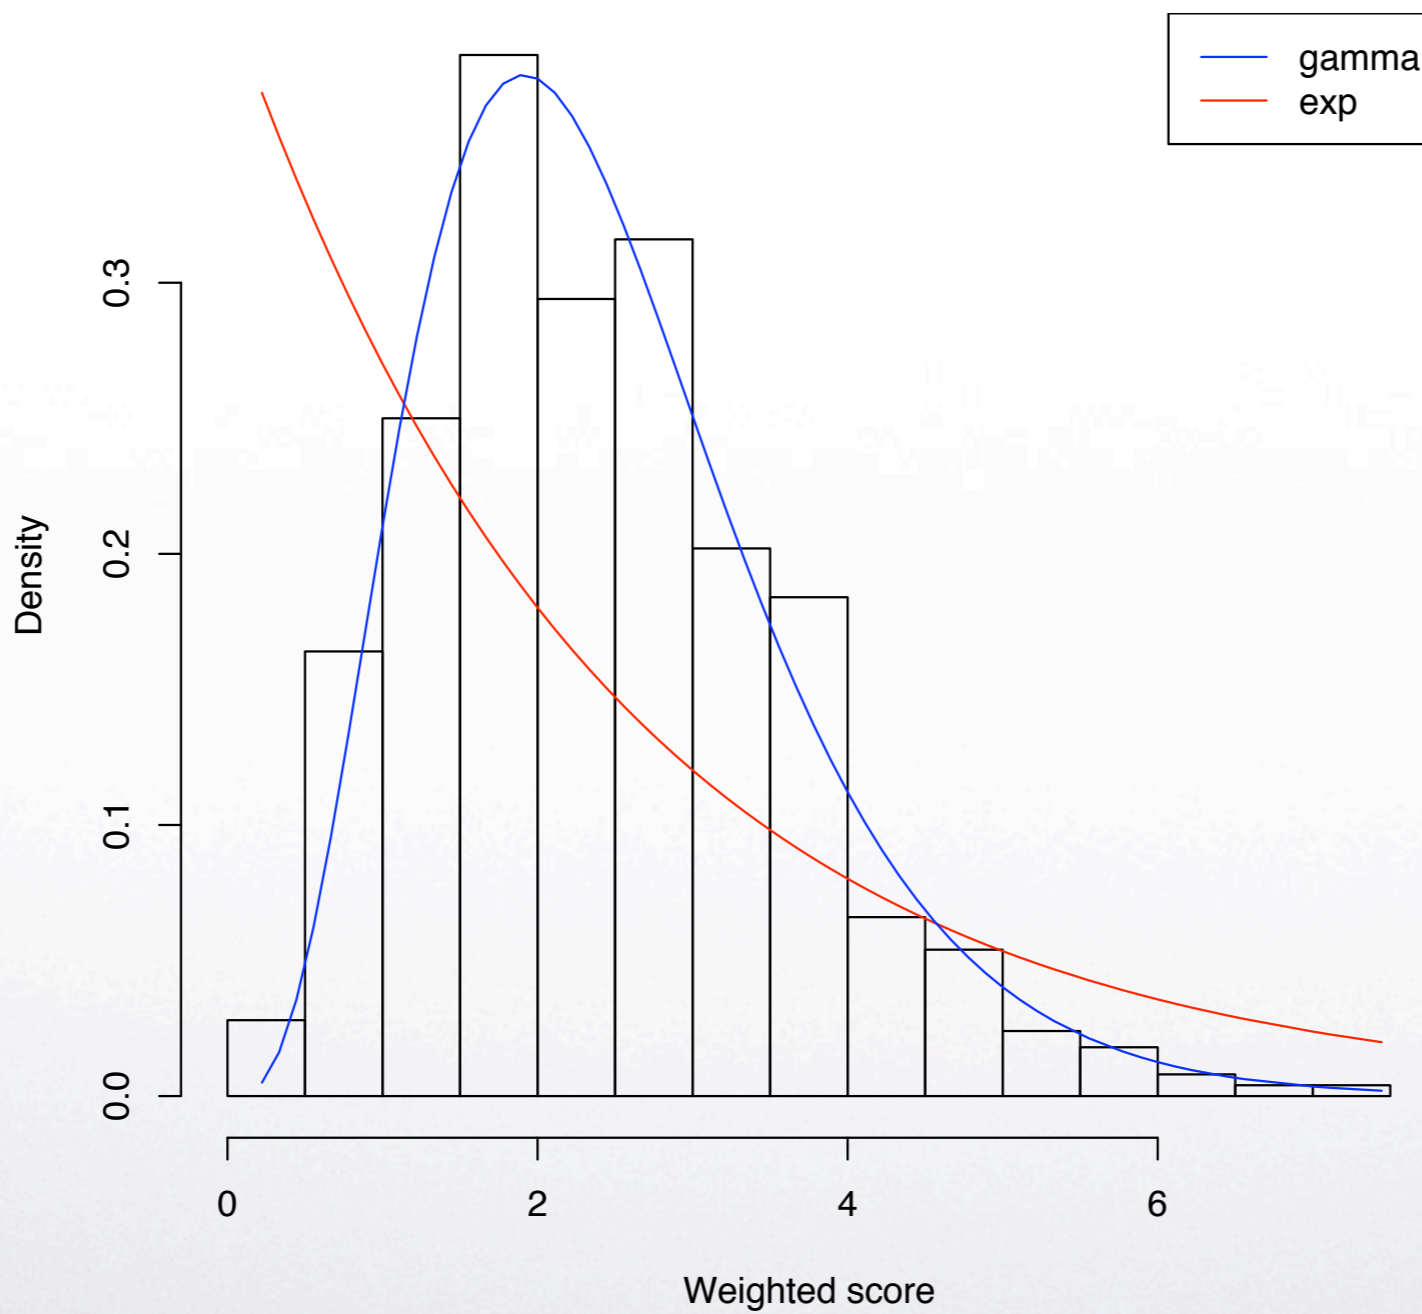

Assessment of significance

Distribution of randomized weighted scores for a group of size 7

Group	Group	Size	Average score p-value	Max score p-value	Gene-weight score p-value
104	integrin alpha	7	0.0858	1.23E-06	3.62E-05
1128	myc	5	0.0044	0.0003	2.72E-05

Significance of the number of groups

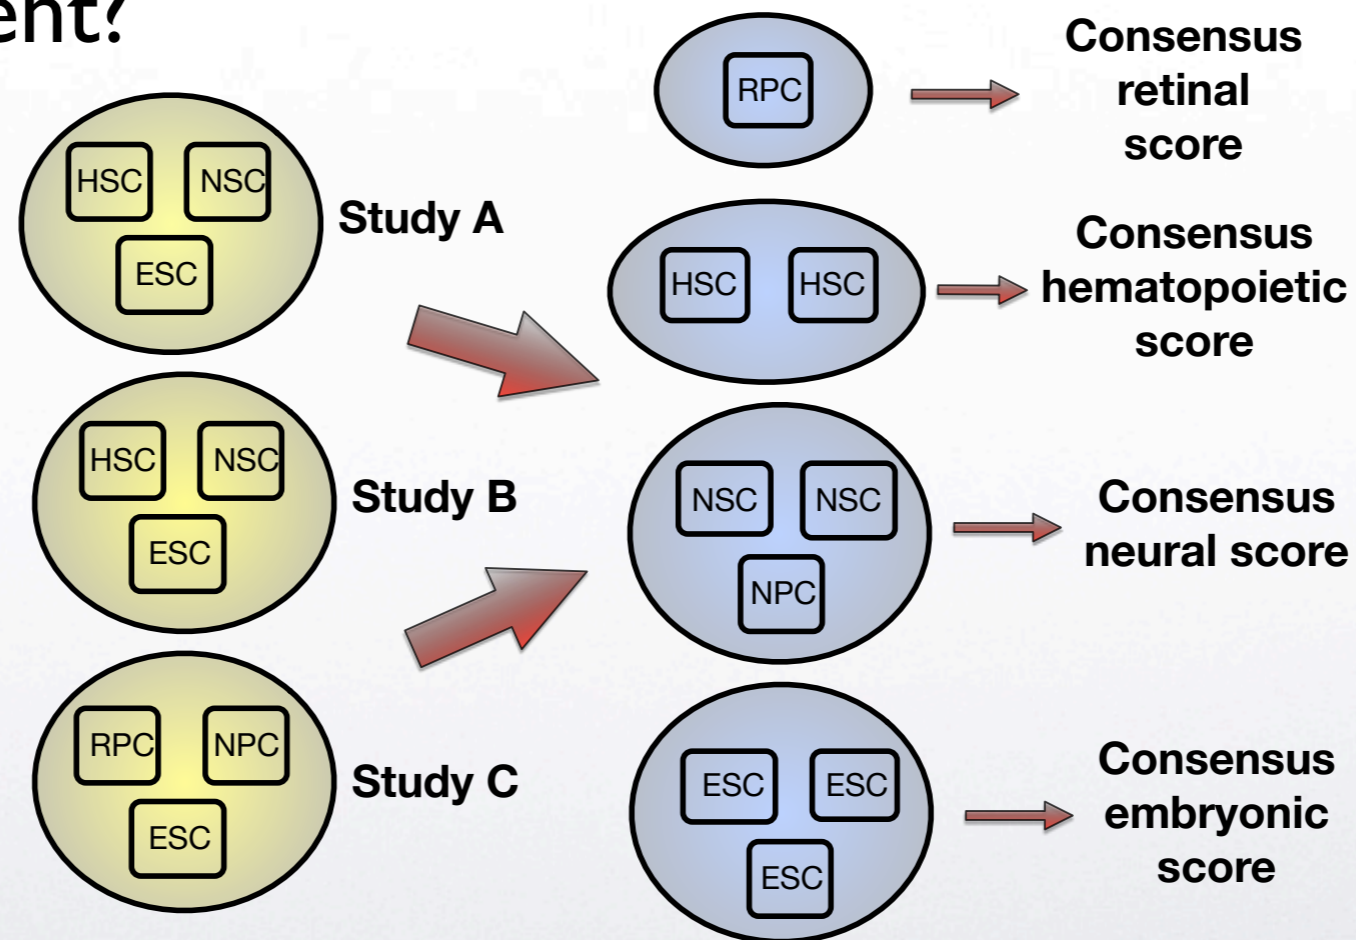

Distribution of the number of common homolog groups to all populations in random data

Transformation of data

- Are data points (expression in same population) independent?

 polyhomeotic-like family (2 genes)
 Hey1 (1 gene)

Initial pathway analysis

- 354 pathways from Biocarta and Kegg
- 1551 genes represented
- 73 common pathways - at least one gene overexpressed in each experiment
- Initial assessment: is there a significant number of genes from the pathway among the upregulated genes in each experiment?

Distribution of pathways with significant number of upregulated genes

- Signaling
- Basal machinery
- Biosynthesis
- Degradation
- Metabolism
- Cell cycle-related/checkpoint-related
- Aging/immortality/telomerase
- Other

Future work

- Short-term
 - ✓ Homolog analysis - look for TFBS, PFAM domains, or other features that distinguish upregulated from non-upregulated genes
 - ✓ Homolog analysis - cluster groups after reduction of data and distinguish between “single gene-strong expression” group pattern and “many genes-weak expression” group pattern
 - ✓ Pathway analysis - Assess significance of scores for individual pathways
- Long-term
 - ✓ Look for ES-specific, neural-specific, hematopoietic-specific groups (already done within homolog analysis)
 - ✓ Incorporate other stem cell data (2 more studies already compared)
 - ✓ Incorporate downregulated data
